

Slide 1

Introduction to Bacteria Monitoring of Surface water for Volunteers

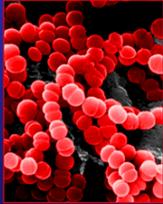

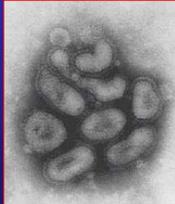

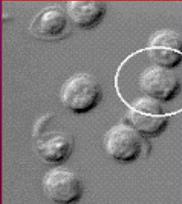

CWQ Winter
Session
February 7, 2004

Slide 2

Is the water safe?

In part, the answer to this ? depends on presence or absence of pathogens in surface water associated with fecal waste (including bacteria, viruses, and protozoans) that can cause illnesses in humans.

		
Bacteria (Streptococcus)	Viruses (Norovirus, Hepatitis A)	Protozoa (Cryptosporidium)

Slide 3

Sources of fecal contamination to water bodies

- Wildlife
- Human activities:
 - Human sewage:
 - Leaky septic systems
 - "straight pipes"
 - Poorly designed/maintained sanitary sewer or WWTPs
 - Agricultural waste:
 - "direct deposit" from farm animals - lack of stream side fencing
 - Improper manure application
 - Poorly constructed/maintained waste storage

Slide 4

Human uses of surface water are pathways for disease . . .

- Irrigation
Eating raw crops > human diseases
- Drinking
Dysentery, gastroenteritis, hepatitis, typhoid
- Recreation
Immersion > infections
Eyes, ears, nose, throat, digestive system problems
- Eating
Shellfish consumption

Slide 5

Why not monitor directly for Pathogens?

- Impractical - too many pathogens
- Methods for some not available
- Labor intensive and expensive
- Long time for results
- Inconsistent concentrations - episodic

- Instead, look for indicators of these pathogens

Slide 6

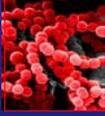

Good Indicator Criteria for Fecal contamination of Waterbody:

- High correlation between presence of indicator with presence of pathogens, ie likelihood that illness would occur
- Indicator should have survival time longer than pathogen
- Indicator shouldn't continue to grow on its own in water - indicator concentration should have correlation to degree of pollution
- Testing method should be easy to perform and relatively inexpensive

Slide 7

Most commonly used bacterial indicators associated with intestines and feces of warm-blooded animals:

←————→

Coliform Group	Fecal Streptococcus Group
	
<ul style="list-style-type: none">• Total coliforms• Fecal coliforms• <i>Escherichia coli</i>	<ul style="list-style-type: none">• Enterococcus

Slide 8

What are bacteria?

Bacteria

- Single-celled microorganisms with no membrane around the nucleus and a single strand of DNA.
- Multiply by splitting into 2 daughter cells

Cholera
Typhoid Fever
Legionnaire's Disease

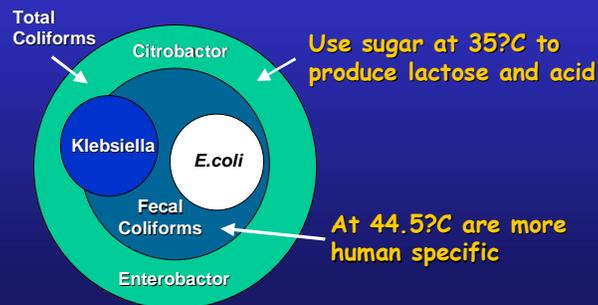

Slide 9

Not all Bacteria are bad !

- Bacteria have important role in the aquatic ecosystem:
 - Decomposition: break down plant and animal remains releases nutrients back into food web
 - Serve as food for other organisms
 - Involved in important chemical conversions in water

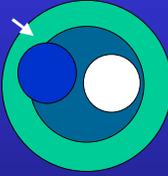

Slide 10

The Coliform Bacteria Group

Slide 11

Total Coliforms

The diagram shows a large green circle with a white arrow pointing to it from the label 'Total Coliforms'. Inside this green circle are two smaller circles: one blue and one white.

- Not useful for testing recreational or shellfishing waters- Some total coliforms are naturally found in plant material or soil, in addition to feces, so their presence doesn't necessarily indicate fecal contamination.
- Total coliforms are useful for testing drinking water (regulated by VA Department of Health), where contamination by soil or plant material would still be a problem

Slide 12

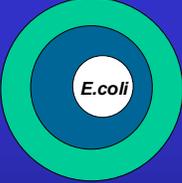

Fecal Coliforms

The diagram shows a green circle with a white arrow pointing to it from the label 'Fecal Coliforms'.

- More Fecal specific but still includes fecal and non fecal bacteria despite the name
 - Klebsiella not necessarily fecal (associated with textile, pulp and paper mill wastes)
 - Was only indicator for surface water quality standards in VA until recently (still is in many states)

Slide 13

Escherichia Coli (E. Coli)

- Occurs only in the feces of warm blooded mammals
- Based on 1986 EPA study, presence of E.Coli in freshwater had a much higher correlation with presence of human pathogens (0.8), whereas basically no correlation for Fecal coliform (-.08) - therefore, EPA recommends as best indicator of health risk for freshwater recreation

Slide 14

Enterococcus

- Another group of bacteria (not a coliform) also found in intestinal tract of warm-blooded animals
- Salt tolerant (E. coli not as salt tolerant)
- Based on 1986 EPA study, presence of Enterococci in both marine and freshwater had a very high correlation with presence of human pathogens (0.75 marine and .74 freshwater). Therefore, EPA recommends as best indicator of health risk for marine recreation

Slide 15

Bacteria Water Quality Standards

- Drinking water standards - regulated by VA Department of Health - the Maximum Contaminant Level (MCL) for Total Coliforms (includes Fecal and E.Coli) is 0 colonies/ 100 ml.
- Shellfish waters - criteria established by FDA and monitored by Virginia Department of Health. FDA requires analysis of fecal coliforms. Geometric mean shall not exceed MPN of 14/100 ml

Slide 16

VA Surface Water Standards for Bacteria

- Bacteria Criteria designed to protect *Recreational Uses*
- Phasing out of Fecal coliform standard by 2008
- Effective January 2003, Standards developed for primary recreation uses for E.Coli for freshwater and enterococci for saltwater and *transitional* waters

Slide 17

Fecal Coliform standard

- Geometric mean (applies if 2 or more samples collected during calendar month)
maximum of 200 colonies/100 ml

- or 400 colonies/100 ml for >10% of samples per calendar month

- These criteria will not apply after 2008, or if 12 or more samples have been collected at a site, whichever comes first

Slide 18

E.Coli surface water standard for Primary recreational use

	Geometric Mean	Single Sample maximum
E.Coli (Freshwater)	126	235
Enterococci (Saltwater and transition zone)	35	104

Geometric mean applies when 2 or more samples collected in a calendar month

Slide 19

Geometric Mean

Reduces the influence of very high numbers on a data set . . .

- Data are transformed to log values
- Log values are averaged
- Results transformed back into original units
- Microsoft Excel can calculate geometric mean- choose function *geomean*

Slide 20

E.Coli surface water standard for Secondary recreational use

	Geometric Mean	Single Sample maximum
E.Coli (Freshwater)	630	1173
Enterococci (Saltwater and transition zone)	175	519

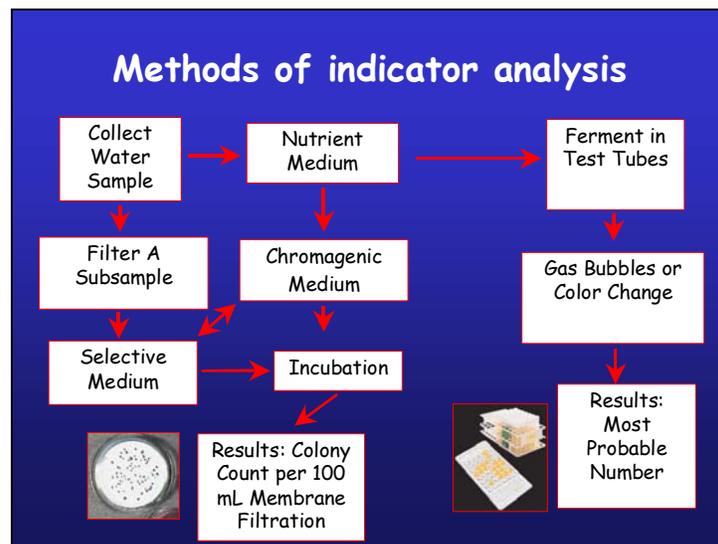

Effective Feb 12, 2004

Slide 21

Secondary contact recreation:

- A water-based form of recreation, the practice of which has a low probability for total body immersion or ingestion of waters
- Ex: wading, boating fishing
- No secondary waters have been identified as of yet- primary uses can not be removed if use can be attained through point source controls and cost effective and reasonable BMPs. Use attainability analysis would have to be performed- very rigorous procedure

Slide 22

Slide 23

Methods of indicator analysis

•Membrane Filtration (MF): more commonly used than MPN - used by DEQ for assessment. Less labor intensive, less expensive than MPN. Unit is colonies/ml

•Most Probable Number (MPN): used for shellfish monitoring by VDH

•Both are laboratory procedures and can be used for either E. Coli or Enterococci

Slide 24

Methods of indicator analysis - options for volunteer groups:

•EPA Approved or Standard Methods:

- MF
- MPN

•Modified MPN: Idexx Collilert, Colilert-18 (both analyze E.Coli), and Enterolert (analyzes Enterococci)

•For use by DEQ for assessment, QAPP must be prepared which includes field collection procedures and lab standard operating procedures approved by DEQ

•Could set up own program- probably best to partner with private lab, college/university

Slide 25

Methods of indicator analysis – options for volunteer groups:

- Alternatives to laboratory analysis of E. Coli:
 - Coliscan Easygel method- for E. Coli - similar to MF but filtration not required and can read without microscope
 - good for volunteers for *screening purposes* and assist with source tracking - not currently approved by DEQ for assessment purposes

Slide 26

Which indicator/method to use?

- Freshwater? Saltwater/brackish?
- For what will you use the results?
- Screening v. assessment
- Source identification?
- Equipment, time, cost
- Quality control

Slide 27

Other Options

- Test for other indicators of presence of sewage (e.g. optical brighteners)
 - Place unbleached cotton pads in stream
 - Retrieve pads
 - Check for fluorescence

Slide 28

References and Assistance:

- Assistance provided by DEQ and VDH
- River Network, Geoff Dates
- The Volunteer Monitor newsletter by EPA
